(54) Controlling access to objects in an information handling system

(57) A system, method and article of manufacture for controlling access to objects in an information handling system employing object oriented technology, includes one or more processors (12), a memory system (14), one or more I/O controllers (24) each controlling one or more I/O devices (18,20,22), a bus (16) connecting the processors (12), the memory system (14) and the I/O controllers (24), an operating system controlling operation of the processors (12), the memory system (14) and the I/O controllers (24), and an object oriented control means which includes a BeforeAfter metaclass having a control element which is used to control access to objects. A secure metaclass is defined to be a subclass of the BeforeAfter metaclass. The secure metaclass overrides the Before method to perform authorisation checking prior to method dispatching. This controls access to protected classes which are subclasses of the secure metaclass.

FIG. 1

GB 2 308 688 A

FIG. 1

FIG. 2

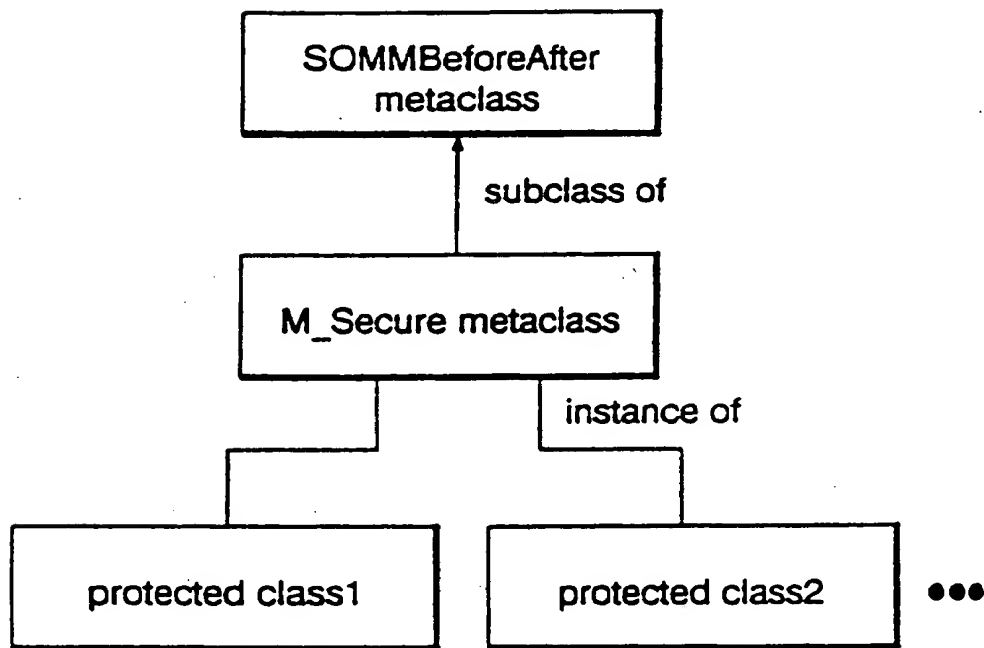

FIG. 3

CONTROLLING ACCESS TO OBJECTS IN AN INFORMATION HANDLING SYSTEM

The present invention relates to information handling
5 systems, methods and articles of manufacture, and more
particularly to information handling systems, methods and
articles of manufacture for protecting objects by access
control in an object oriented system.

There is a need to protect access to objects in an
10 object oriented system.

Traditionally, resource managers represent the control
point for enabling access authorisation checking. On a
request for accessing a resource in a data processing
system, its resource manager takes control, and if the
15 underlying resource is protected, the access checking
process is triggered, after which the requested access is
either granted or stopped from proceeding. For instance, on
a file opened, resulting from a print instruction of a
user's program, the file system invokes an authorisation
20 checking routine that verifies that the user has the right
for writing into the corresponding file.

In object oriented systems, with resources being object
instances, there is no such traditional concept of resource
managers that would take control on every attempt to invoke
25 a method, or send a message, to a protected object.

The problem, as it relates to a certain class of object
oriented systems, is finding a way of automatically
triggering access checking on a method invocation on a
protected object. It is required that any solution be safe
30 from client tampering, that is, the client should not be
able to effect or disrupt automatic triggering of
authorisation checking.

In the prior art there are many techniques for improving object oriented programming systems (OOPS).

The following are examples of the prior art.

U.S. Patent 4,525,780 teaches a data processing system
5 having a memory organised into objects, where the system
uses a protection technique to prevent unauthorised access
to objects by users which are identified by a subject number
identifying the user, a process for executing a user's
procedure and the type of system operation to be performed
10 by the user's procedure. An access control list is
maintained to control access to objects based on subject
identifier.

Although the patent generally deals with methods for
protecting access to objects in object oriented programs,
15 the patent does not teach nor suggest using a metaclass in
an object oriented system to control access to objects as is
taught and claimed herein with reference with the present
invention.

U.S. Patent 5,136,712 teaches an object based operating
20 system for a multitasking computer system including means
for making an object private to a process. Access to a
private object is controlled by an access control list.

Although the patent generally deals with methods for
protecting access to objects in object oriented programs,
25 the patent does not teach nor suggest using a metaclass in
an object oriented system to control access to objects as is
taught and claimed herein with reference with the present
invention.

U.S. Patent 5,265,221 teaches an access control
30 mechanism for granting, revoking, and denying authorisation

to objects using a system of verbs, parameters, attributes and functions.

Although the patent generally deals with methods for protecting access to objects in object oriented programs, the patent does not teach nor suggest using a metaclass in an object oriented system to control access to objects as is taught and claimed herein with reference with the present invention.

U.S. Patent 5,297,283 and US Patent 5,321,841 appear to teach the same system as US Patent 5,136,712 discussed above.

Although the patent generally deals with methods for protecting access to objects in object oriented programs, the patent does not teach nor suggest using a metaclass in an object oriented system to control access to objects as is taught and claimed herein with reference with the present invention.

U.S. Patent 5,093,914 generally teaches a method used by a digital computer in controlling execution of an object oriented program to effect a defined action, for example, stopping the program when a specified virtual function is invoked on a specified object during execution of the program.

Although the patent generally deals with methods for protecting access to objects in object oriented programs, the patent does not teach nor suggest using a metaclass in an object oriented system to control access to objects as is taught and claimed herein with reference with the present invention.

U.S. Patent 5,343,554 teaches a computing system in which problems are solved by a process which includes

creating objects of first and second classes wherein the second class objects are externally invocable and where the externally invocable sub-class objects include an indication of an internally invocable sub-class object and executing
5 the class of objects wherein one externally invocable sub-object invokes the internally invocable sub-object and a new object of the first class is generated in response to the results.

Although the patent generally deals with methods for
10 protecting access to objects in object oriented programs, the patent does not teach nor suggest using a metaclass in an object oriented system to control access to objects as is taught and claimed herein with reference with the present invention.

15 An overall goal in object oriented programming systems is the development of program objects which can be reused easily.

The importance of binary code over source code increases with the degree of reuse. A main purpose of
20 object oriented technology is code reuse. For object oriented technology to achieve large scale success, binary code reuse is essential. As the state of the art moves towards applications built from object formats which can be tailored and plugged into each other, binary code is
25 critical.

The Object Management Group is defining a set of interfaces for object system services named Common Object Services.

It is an object of the present invention to protect
30 objects in an object oriented system by controlling access to objects.

According to the first aspect of the present invention, there is provided a method for controlling access to objects in an information handling system employing object oriented technology, comprising the steps of defining a secure
5 metaclass; invoking a first class as a metaclass of the secure metaclass; and controlling access to one or more protected classes which are subclasses of the secure metaclass in response to values returned on invoking the first class.

10 According to the second aspect of the present invention, there is provided a computer readable medium comprising means for controlling access to objects in an information handling system employing object oriented
15 technology, the means comprising means for defining a secure metaclass; means for invoking a first class as a metaclass of the secure metaclass; and means for controlling access to one or more protected classes which are subclasses of the secure metaclass in response to values returned on invoking the first class.

20 According to the third aspect of the present invention, there is provided an information handling system, employing oriented technology, for controlling access to objects comprising one or more processors; a memory system; one or
25 more I/O controllers each controlling one or more I/O devices; a bus connecting the processors, the memory system and the I/O controllers; an operating system controlling operation of the processors, the memory system and the I/O controllers; means for defining a secure metaclass; means
30 for invoking a first class as a metaclass of the secure metaclass; and means for controlling access to one or more protected classes which are subclasses of the secure metaclass in response to values returned on invoking the first class.

It is an advantage of the present invention that object security can be readily achieved by creation of a secure metaclass which performs authorisation checking prior to method dispatch.

5 The invention will now be described, by way of example, with reference to the accompanying drawings, in which:

Figure 1 is a block diagram of a system for executing the method according to the present invention.

10 Figure 2 is a block diagram showing the operating system platform and system object model program supporting the present invention.

Figure 3 is an object diagram of the preferred embodiment of the present invention.

15 Referring now to Figures 1 and 2, an information handling system 10 and an operating system environment for the present invention will be described.

Information handling system 10 may be a graphics work station or the like with a very powerful processor 12, a storage system 14, a system bus 16, display sub-system 18
20 controlling a display device 20, a cursor control device 22, and an I/O controller 24, all connected by system bus 16. The information handling system 10, shown in Figure 1 may be operated by a commercially available well known multitasking operating system such as OS/26 (OS/2 is a registered
25 trademark of International Business Machines Corporation). Among many tasks which the OS/2 operating system 26 controls on operating information handling system 10, is execution of a program SOMObjects 28, which is a commercially available product of International Business Machines Corporation.

The method and article of manufacture of the present invention may be incorporated in the SOMObjects program. As used herein, SOM means system object model.

5 An important aspect of any object oriented system is making the object secure, so that object/method granularity access control can be enforced. This involves checking access control in a before method.

The present invention may be efficiently embodied in Distributed SOM (DSOM) (across address space ORB) and
10 Security SOM (SSOM).

The way the user specifies security is to specify the following constraints when searching for a class object:

name: secure

15 value: A boolean indicating whether the object is protected by access control checking.

name: ACL

value: If secure==TRUE, an access control list.

20 When granularity is per method, enforcement can be done either per method invocation or when a reference is first obtained (the capability approach). The present invention provides enforcement on method invocation.

25 A class is also an object whose class is a metaclass. A class object, then, being an instance of its metaclass, responds to the methods that its metaclass defines. A metaclass, like any other class, can be subclassed and its methods be overridden. All metaclasses are ultimately derived from the root metaclass.

Referring now to the object diagram of Figure 3, the preferred embodiment of the present invention will be described. One run time metaclass is a BeforeAfter metaclass. When a class is created from the BeforeAfter metaclass 32, two methods are transparently executed on every invocation of method M on an object of class C. One method executes before the method is invoked, the Before method and the other method, the After method, executes following the execution of method M. The Before method and the After method are defined by the BeforeAfter metaclass 32. These two methods can be overridden in a metaclass 34 derived from the BeforeAfter metaclass to allow for a special function to be performed.

On invocation, the Before method returns a boolean value (1 or 0). If this value is TRUE (1), then normal processing occurs, that is, the execution of the primary method M, followed by the execution of the After method. If the boolean value is not TRUE (0), neither the primary method M nor the After method are executed. Thus, the BeforeAfter metaclass 32 is the key to controlling method execution on protected objects 36, 38.

A secure metaclass 34 (M_Secure) is defined to be a subclass of BeforeAfter metaclass 32. In M_Secure, the Before method of metaclass 32 is overridden to perform authorisation checking prior to dispatch of the Before method from metaclass 32. A protected class 36, 38 is a class whose metaclass is M_Secure 34. M_Secure overrides BeforeMethod to perform the following function:

```

BeforeMethod(M_secure    Self,
30      Environment      *ev,
      Object             object,

```

{

```
return access_allowed(...,  
        principal_security_attributes,  
        primaryMethod_security_attributes,  
        object_security_attributes)
```

15

Note that the solution cannot be tampered with by the client application as the access decision is performed on the server side during the attempt to dispatch the method.

CLAIMS

1. A method for controlling access to objects in an information handling system employing object oriented technology, comprising the steps of:

5 defining a secure metaclass (34);
 invoking a first class (32) as a metaclass of the
secure metaclass (34); and
 controlling access to one or more protected classes
 (36,38) which are subclasses of the secure metaclass (34)
10 in response to values returned on invoking the first class
 (32).

2. A method according to claim 1, wherein the step of controlling access further comprises the steps of:

15 overriding dispatch of any method invoked by the
 invoking step; and
 checking authorisation for access to an object in a
protected class (36,38) prior to method dispatching.

20 3. A method according to claim 2, wherein the step of
controlling access further comprises the step of:

 dispatching an invoked method if the checking
 authorisation step indicates authorised access to a
protected class (36,38).

25

4. A method according to claim 1, 2 or 3, wherein the
invoking step further comprises the steps of:

 invoking a before method on the secure metaclass (34);
 testing a value returned by the before method;

if the value returned is true, proceeding with normal processing; and

if the value returned is not true, inhibiting further processing.

- 5 5. A computer readable medium comprising means for controlling access to objects in an information handling system employing object oriented technology, the means comprising:

means for defining a secure metaclass (34);

- 10 means for invoking a first class as a metaclass (32) of the secure metaclass (34); and

- means for controlling access to one or more protected classes (36,38) which are subclasses of the secure metaclass (34) in response to values returned on invoking the first class (32).
- 15

6. A computer readable medium, according to claim 5, wherein said means for controlling access further comprises:

- 20 means for overriding dispatch of any method invoked by the invoking means; and

means for checking authorisation for access to an object in a protected class (36,38) prior to method dispatching.

- 25 7. A computer readable medium, according to claim 6, wherein said means for controlling access further comprises:

means for dispatching an invoked method if the checking authorisation means indicates authorised access to a protected class (36,38).

30

8. A computer readable medium, according to claim 5, 6 or 7, wherein said means for invoking further comprises:

means for invoking a before method on the secure metaclass (34);

means for testing a value returned by the before method;

5 means for proceeding with normal processing if the value returned is true; and

means for inhibiting further processing if the value returned is not true.

10 9. An information handling system, employing oriented technology, for controlling access to objects comprising:

one or more processors (12);

a memory system (14);

15 one or more I/O controllers (24) each controlling one or more I/O devices (18,20,22);

a bus (16) connecting the processors (12), the memory system (14) and the I/O controllers (24);

20 an operating system (26) controlling operation of the processors (12), the memory system (14) and the I/O controllers (24);

means for defining a secure metaclass (34);

means for invoking a first class (32) as a metaclass of the secure metaclass (34); and

25 means for controlling access to one or more protected classes (36,38) which are subclasses of the secure metaclass (34) in response to values returned on invoking the first class (32).

30 10. An information handling system, according to claim 9, wherein said means for controlling access further comprises:

means for overriding dispatch of any method invoked by the invoking means;

means for checking authorisation for access to an object in a protected class (36,38) prior to method dispatching; and

5 means for dispatching an invoked method if the checking authorisation means indicates authorised access to a protected class (36,38).
